Title Piecewise Smooth Regression by Bootstrapped Binary Segmentation

Version 1.0-1
<b>Depends</b> R (>= $3.0.0$ )
<b>Imports</b> Rcpp (>= 0.12.3), stats
LinkingTo Rcpp
Suggests knitr
VignetteBuilder knitr
Description Provides methods for piecewise smooth regression. A piecewise smooth signal is estimated by applying a bootstrapped test recursively (binary segmentation approach). Each bootstrapped test decides whether the underlying signal is smooth on the currently considered subsegment or contains at least one further change-point.

BinSegBstrap-package Piecewise smooth regression by bootstrapped binary segmentation

## **Description**

Provides methods for piecewise smooth regression. The main function BinSegBstrap estimates a piecewise smooth signal by applying a bootstrapped test recursively (binary segmentation approach). A single bootstrapped test for the hypothesis that the underlying signal is smooth versus the alternative that the underlying signal contains at least one change-point can be performed by the function BstrapTest. A single change-point is estimated by the function estimateSingleCp. More details can be found in the vignette. Parts of this work were inspired by Gijbels and Goderniaux (2004).

## Acknowledgement

This work results from a summer research project at the University of Cambridge in 2019. Kate McDaid was supported by a bursary from the summer research programme of the Centre of Mathematics at the University of Cambridge. Florian Pein's position is funded by the EPSRC programme grant 'StatScale: Statistical Scalability for Streaming Data'.

# Examples

```
n <- 200
signal <- sin(2 * pi * 1:n / n)
signal[51:100] <- signal[51:100] + 5
signal[151:200] <- signal[151:200] + 5

y <- rnorm(n) + signal

est <- BinSegBstrap(y = y)

plot(y)
lines(signal)
lines(est$est, col = "red")

n <- 100
signal <- sin(2 * pi * 1:n / n)
signal[51:100] <- signal[51:100] + 5</pre>
```

BinSegBstrap 3

```
y <- rnorm(n) + signal

test <- BstrapTest(y = y)
est <- estimateSingleCp(y = y)

plot(y)
lines(signal)
lines(est$est, col = "red")</pre>
```

BinSegBstrap

Estimates a piecewise smooth signal

#### **Description**

A piecewise smooth signal is estimated by applying BstrapTest recursively (binary segmentation approach). The final estimator is estimated by kernel smoothing on each segment separately; a joint bandwidth is selected by crossvalidation. More details can be found in the vignette.

## Usage

# **Arguments**

a numeric vector containing the data points У bandwidth the bandwidth, i.e. a numeric with values between 1 / length(y) and 0.5. If missing  $\exp(seq(log(10 / length(y)), log(0.25), length.out = nbandwidth))$ will be used. Crossvalidation will be performed if it is not a single numeric. Note that the test has almost no power when the bandwidth for the kernel smoother is too small, since then a change-point can be approximated well by a quickly changing smooth function. nbandwidth a single integer giving the number of bandwidths (see above) if bandwidth is missing В a single integer giving the number of bootstrap samples a probability, i.e. a single numeric between 0 and 1, giving the significance level alpha of the test kernel the kernel function, i.e. either a string or a function that takes a single numeric

vector and returns the values of the kernel at those locations

#### Value

- a list with the following components:
- est: the estimated signal
- cps: the estimated change-point locations
- bandwidth: the selected bandwidth

4 BstrapTest

## **Examples**

```
n <- 200
signal <- sin(2 * pi * 1:n / n)
signal[51:100] <- signal[51:100] + 5
signal[151:200] <- signal[151:200] + 5

y <- rnorm(n) + signal

# default bandwidth and kernel
est <- BinSegBstrap(y = y)

plot(y)
lines(signal)
lines(est$est, col = "red")

# fixed bandwidth
est <- BinSegBstrap(y = y, bandwidth = 0.1)

# user specified kernel
kernel <- function(x) 1 - abs(x) # triangular kernel
est <- BinSegBstrap(y = y, kernel = kernel)</pre>
```

BstrapTest

Bootstrap test for a single change-point

## **Description**

Tests whether the underlying signal is smooth or contains at least one change-point. The smooth alternative is estimated by a (crossvalidated) kernel smoother. The single change-point alternative is estimated by estimateSingleCp. Its estimated jump size is used as a test statistic and the critical value is obtained by bootstrapping. More details can be found in the vignette.

# Usage

## **Arguments**

a numeric vector containing the data points

bandwidth

the bandwidth, i.e. a numeric with values between 1 / length(y) and 0.5. If missing  $\exp(\log(10 / \text{length(y)}), \log(0.25), \text{length.out} = \text{nbandwidth)})$  will be used. Crossvalidation will be performed if it is not a single numeric. Note that the test has almost no power when the bandwidth for the kernel smoother is too small, since then a change-point can be approximated well by a quickly changing smooth function.

BstrapTest 5

nbandwidth	a single integer giving the number of bandwidths (see above) if bandwidth is missing
В	a single integer giving the number of bootstrap samples
alpha	a probability, i.e. a single numeric between 0 and 1, giving the significance level of the test
kernel	the kernel function, i.e. either a string or a function that takes a single numeric vector and returns the values of the kernel at those locations

#### Value

a list with the following components:

- piecewiseSignal: the estimated signal with a single change-point
- cp: the estimated change-point location
- size: the estimated jump size
- bandwidth: the selected bandwidth for the piecewise signal
- bandwidthSmooth: the selected bandwidth for the smooth signal
- smoothSignal: the estimated smooth signal
- critVal: the by bootstrapping obtained critical value
- pValue: the p-Value of the test
- outcome: a boolean saying whether the test rejects the hypothesis of a smooth signal

# **Examples**

```
n <- 100
signal <- sin(2 * pi * 1:n / n)</pre>
signal[51:100] <- signal[51:100] + 5
y <- rnorm(n) + signal
# default bandwidth and kernel
test <- BstrapTest(y = y)</pre>
if (test$outcome) {
  # null hypothesis of a smooth signal is rejected
  estimatedSignal <- test$piecewiseSignal</pre>
} else {
  # null hypothesis of a smooth signal is accepted
  estimatedSignal <- test$smoothSignal</pre>
}
plot(y)
lines(signal)
lines(estimatedSignal, col = "red")
# fixed bandwidth
test <- BstrapTest(y = y, bandwidth = 0.1)</pre>
# user specified kernel
kernel <- function(x) 1 - abs(x) # triangular kernel</pre>
test <- BstrapTest(y = y, kernel = kernel)</pre>
```

Estimation of a single change-point

## **Description**

Estimates a single change-point in an otherwise smooth function. The change-point location is estimated as the maximum of the differences of left and right sided running means. The estimate left and right of the change-point are obtained by kernel smoothers. Windows of the running mean and kernel bandwidth are chosen by crossvalidation. More details can be found in the vignette.

## Usage

# **Arguments**

y a numeric vector containing the data points

bandwidth the bandwidth, i.e. a numeric with values between 1 / length(y) and 0.5. If

missing  $\exp(seq(log(2 / length(y)), log(0.25), length.out = nbandwidth))$ 

will be used. Crossvalidation will be performed if it is not a single numeric

nbandwidth a single integer giving the number of bandwidths (see above) if bandwidth is

missing

kernel the kernel function, i.e. either a string or a function that takes a single numeric

vector and returns the values of the kernel at those locations

#### Value

- a list with the following components:
- est: the estimated function with a single change-point
- cp: the estimated change-point location
- size: the estimated jump size
- bandwidth: the selected bandwidth

# Examples

```
n <- 100
signal <- sin(2 * pi * 1:n / n)
signal[51:100] <- signal[51:100] + 5
y <- rnorm(n) + signal
# default bandwidth and kernel
est <- estimateSingleCp(y = y)
plot(y)</pre>
```

estimateSingleCp 7

```
lines(signal)
lines(est$est, col = "red")

# fixed bandwidth
est <- estimateSingleCp(y = y, bandwidth = 0.1)

# user specified kernel
kernel <- function(x) 1 - abs(x) # triangular kernel
est <- estimateSingleCp(y = y, kernel = kernel)</pre>
```
